

How the HMM actually discriminates: only diagnostic positions matter

Most of the 5290 bp transcript is the same in all 7 copies. The discrimination comes from a small subset of positions where the transcripts differ.

A The read

Most of these 5290 bp are identical across all 7 GOLGA8I copies. Skip them – only the diagnostic columns below contribute to assignment.

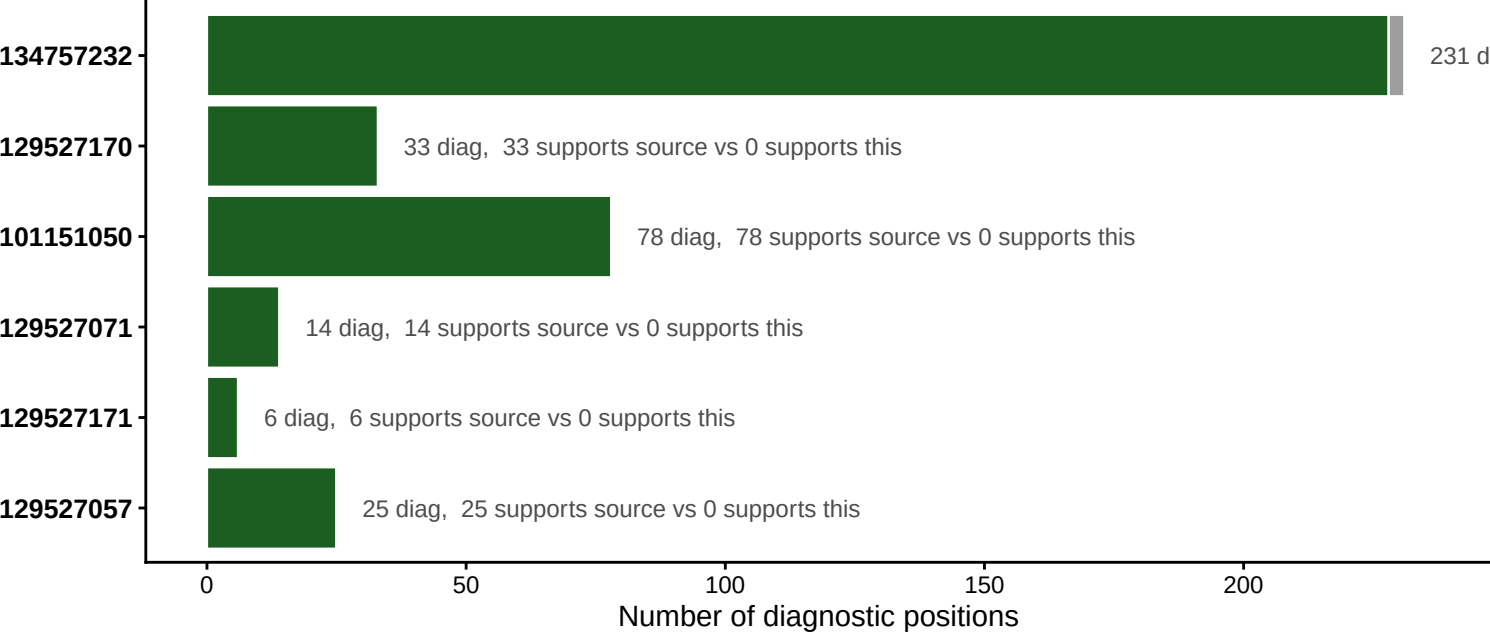

B Diagnostic positions per copy

Each tick = one position where this copy's transcript differs from source. Conserved positions are NOT shown.

C Evidence count at diagnostic positions

All 6 non–source copies have MANY diagnostic positions, and read R supports SOURCE at almost all of them.

D Net log-odds for SOURCE at diagnostic positions

Positive = read supports SOURCE more than this copy. Larger = more confident.
