

GOLGA8I read-to-copy assignment: variant-position fingerprint

The conserved part of the transcript is ignored. Only positions where the 7 copies disagree carry information. The read's base at each variant position 'votes' for one or more copies – the source wins because it matches at (almost) every position.

Read R = 101150678 transcript (5288 bp) with 2% noise. 139 clean variant positions across 7 copies – we show 24 of them (one per bin, highest-entropy).

B Fingerprint matrix at variant positions

Each column = one variant position (bp coordinate in source transcript). Each row = one copy's nucleotide at that position. Green-bordered cells = same base as the READ.

C Matches with READ at displayed variant positions

Source copy matches the read at every variant position (within noise). No other copy comes close.
