

* Scored within the read's source family, which is known only in simulation; a user of the output cannot choose that result. Decisive site: a PSV or splice junction, covered by the read, at which the candidate copies differ. NM-identical twin: an alignment at another locus with the best alignment score and the same number of mismatches and indels as the source-copy alignment. Development tables (one contig's catalog per sample); the genome-wide catalogs of all six samples replace them.
